Assume this is because the big clinical dataset only has people with autism, not ADHD.

Only try to link clinical data to records in the schools data for the Southern health service in Araucanía (ARAUC) because that's where the clinical data is from.

```

All the students that can't be uniquely identified (6) are males in Temuco and SES status doesn't help distinguish them.

Probabilistic record linkage

https://rpubs.com/ahmademad/RecordLinkage https://www.bristol.ac.uk/media-library/sites/cmm/migrated/documents/problinkage.pdf https://cran.r-project.org/web/packages/diyar/vignettes/links.html

Mismatch on ses is slightly higher weighted than match on everything. Unclear why and doesn't occur for epiWeights() below.

```
# Try supplying error information. Works better when sex_desc and dob are both in blocking as otherwise
# Still quick for whole school dataset
a2 <- compare.linkage(school,
                      #select(school, -ses_status),

Bit easier to match SES status of 1 (probably more common)

Our matched/non-matched are not different by sex (p-value in Kolmog is same as most of distribution of permuted pvals) but are different by commune and ses status. Cohen's D test isn't suitable to compare the matched and un-matched because the data don't have standard deviations.

??Add commune maps here with size of sample for school and clinical?? Also size of other features.

Then quantify clinical records for ARAUC Sur that haven't been matched.

Dumping ground, don't use below here.

Record linkage using machine learning

Try linkage using ML, as done by Jan van der Laan here https://cran.r-project.org/web/packages/reclin2/vignettes/record_linkage_using_machine_learning.html

In reclin2 package, use ?identical() to see available matching algorithms.

The Jaro-Winkler distance is a string metric for measuring the edit distance between two sequences. It is a variant of the Jaro distance metric proposed by William E. Winkler in 1990 1. The Jaro-Winkler distance uses a prefix scale which gives more favorable ratings to strings that match from the beginning for a set prefix length. The higher the Jaro-Winkler distance for two strings is, the less similar the strings are. The score is normalized such that 0 means an exact match and 1 means there is no similarity 1.

Need to explore different comparator algorithms. Currently it's exact match. Would be good to do communes that are neighbours and ages off by 1.

Try bayesian linkage?

Follow Thomas Stringham https://arxiv.org/pdf/2003.04238.pdf who followed Sadinle https://arxiv.org/abs/1601.06630 Not doing this as limited value when not matching strings.
